# Exact algebraic method for design of the model nonastigmatic spherical ophthalmic glasses 

Tadeusz Kryszczynski<br>Institute of Applied Optics, Department of Geometrical Optics, ul. Kamionkowska 18, 03-805 Warszawa, Poland.

#### Abstract

An exact algebraic method for designing the model nonastigmatic spherical ophthalmic glasses is given. The method allows us to determine construction parameters of glasses with an assumed back vertex power, which completely fulfil all conditions of correct performance, and takes into account manufacture recommendations. The method consists in solving the system of nonlinear equations by means of software. Calculation of the parameters of nonastigmatic spherical ophthalmic glasses of 65 mm in diameter for positive and negative back vertex powers were designed of organic material CR39 in the most interesting range of vertex powers from 0 to $\pm 7$ with 0.25 D step are presented.

## 1. Introduction

This work describes a new approach to the design of model nonastigmatic spherical glasses, so called "punktals". Nonastigmatic ophthalmic glasses are used for correction of the eye refraction errors and they should feature corrected astigmatism in the characteristic field of view with low residual astigmatism in intermediate zones of the field of view. The model version of glasses refers to theoretical solutions and does not include any technological simplifications introduced to reduce the optical tooling.

Design of nonastigmatic lenses has although not rich but a rather long history [1]. In 1801, Young arrived at formulae necessary to calculate the astigmatism of an extremely narrow light beam. In the years 1889-1900, Ostwald used the 3rd order aberration method to design nonastigmatic glasses for infinity and obtained for each glass two solutions differing in the convexity. In 1904, Tscherning presented his 3rd order solutions of nonastigmatic glasses in the form of so-called "Tscherning ellipse". It is also worthwhile to mention design works performed between 1903 and 1914 by Gullstrand and Rohr, and works of Ostwald from 1935 to design the nonastigmatic glasses for near vision. Also Wollaston, Schleiermacher, Martin, Percival, Southall and many others contributed to the development of ophthalmic glasses.

Later for precise calculations of astigmatism trigonometric methods were commonly used, and then came the computer-based methods. Today the 3 rd order aberration methods are no longer in use. In the case of low-power nonastigmatic glasses the angles of incidence on individual surfaces are moderate and smaller than $10-15^{\circ}$,
which explains the past relative usefulness of these methods, especially in situations where tolerances of convexity were rather loose. However the angles of incidence are significant enough to cause deformation compared to the 3rd order aberration calculations.

The new approach presented in this work consists in using exact algebraic equations for computation of nonastigmatic glasses. Besides the correction of astigmatism this method assures that the ophthalmic glasses fulfil exactly all other requirements necessary for proper performance. Hitherto, researchers considered it impossible to give exact algebraic formulae binding the aberrations and astigmatism in particular and its construction and physical parameters. This was due to their extreme complexity. Today we should verify this approach taking into account works of Herzberger [2], Walther [3], [4], Castro-Ramos et al. [5] and the author Kryszczyniski's paper [6] was devoted to algebraic computations in correction of aberrations of simple optical systems (minimum of spherical aberration of single lens, a system of two spherical mirrors with zero spherical aberration at the edge of aperture).

## 2. Meridional pupil ray

The astigmatism of ophthalmic glass is calculated along the meridional pupil ray that determines selected angle of view. During the observation the eye follows the object and rotates. Traditionally it is assumed that the eye's pupil is in its rotation center. In this work, it is assumed that the variables determining the ray tracing in the case of the pupil ray are the consecutive angles of incidence $j_{1}$ and $j_{2}$ of the ray at the glass surfaces. The Figure shows among others also the parameters describing the pupil ray.

Respective refraction angles $j_{1}^{\prime}$ and $j_{2}^{\prime}$ are calculated from the law of refraction, denoting by $n_{1}$ the refractive index of glass. This way we obtain the following formulae:

$$
\begin{equation*}
j_{1}^{\prime}=\arcsin \frac{\sin j_{1}}{n_{1}}, \quad j_{2}^{\prime}=\arcsin \left(n_{1} \sin j_{2}\right) \tag{1}
\end{equation*}
$$

In the meridional plane the angular deviation $D$ of the ray can be calculated equally as the difference of ray angles with the axis or the difference between the angles of incidence and refraction. In this work, the second possibility is employed. Consecutive angular deviations of the ray $D_{1}$ and $D_{2}$ at the glass surfaces can be calculated from the following formulae:

$$
\begin{equation*}
D_{1}=j_{1}-j_{1}^{\prime}, \quad D_{2}=j_{2}-j_{2}^{\prime} \tag{2}
\end{equation*}
$$

Assume that the pupil ray in the object plane forms constant angle $w_{0}$ with the optical axis. Consecutive angles of refraction $w_{1}$ and $w_{2}$ can then be calculated from the following formulae:

$$
\begin{equation*}
w_{1}=w_{0}+D_{1}, \quad w_{2}=w_{0}+D_{1}+D_{2} . \tag{3}
\end{equation*}
$$

Parameters of the pupil ray and differential astigmatic meridional and sagittal rays.
From Equations (1)-(3) it is evident that the angular variables $j_{1}$ and $j_{2}$ describe the angular pupil ray tracing through the ophthalmic glass. To position the ray with respect to the vertex of surfaces we need the coefficients $\mu_{1}$ and $\mu_{2}$ described in the book of Smith [7]. The coefficients are given as follows:

$$
\begin{equation*}
\mu_{1}=\frac{\cos w_{1}+\cos j_{1}^{\prime}}{\cos w_{0}+\cos j_{1}}, \quad \mu_{2}=\frac{\cos w_{2}+\cos j_{2}^{\prime}}{\cos w_{1}+\cos j_{2}} \tag{4}
\end{equation*}
$$

The shortest distance of the ray to the vertex of the first surface we will denote by $M_{1}$ and the center thickness of the glass by $d_{1}$. Then the shortest distance of the ray to the vertex of the second surface $M_{2}$ and $M_{2}^{\prime}$ (before and after refraction) is as follows:

$$
\begin{equation*}
M_{2}=\mu_{1} M_{1}-d_{1} \sin w_{1}, \quad M_{2}^{\prime}=\mu_{2} M_{2}=\mu_{1} \mu_{2} M_{1}-\mu_{2} d_{1} \sin w_{1} . \tag{5}
\end{equation*}
$$

Formulae (1)-(3) show that angular variables $j_{1}$ and $j_{2}$ also describe the location of the pupil ray together with the distance $M_{1}$ and thickness $d_{1}$. Assuming the angular variables $j_{1}$ and $j_{2}$ it is possible to determine the pupil ray tracing not knowing the surface curvatures. Curvatures $c_{1}$ and $c_{2}$ of consecutive glass surfaces depend on the above-mentioned angular and linear variables in accordance with the following formulae:

$$
\begin{equation*}
c_{1}=\frac{\sin w_{0}+\sin j_{1}}{M_{1}}, \quad c_{2}=\frac{\sin w_{1}+\sin j_{2}}{M_{2}} . \tag{6}
\end{equation*}
$$

When calculating astigmatism of ophthalmic lens we also need the oblique thickness along the pupil ray measured between the points of intersection of the ray with surfaces, including the object plane during observation of the near vision $(L \neq 0)$. For that purpose we will need sags $g_{1}$ and $g_{2}$ of intersection points, which can be calculated from the following formulae:

$$
\begin{equation*}
g_{1}=\frac{\sin \left(w_{0}+j_{1}\right)}{\cos w_{0}+\cos j_{1}} M_{1}, \quad g_{2}=\frac{\sin \left(w_{1}+j_{2}\right)}{\cos w_{1}+\cos j_{2}} M_{2} \tag{7}
\end{equation*}
$$

The oblique distance $d_{0}^{*}$ between the object plane and the first surface, and the oblique thickness $d_{1}^{*}$ between the first and the second surfaces can be determined from formulae:

$$
d_{0}^{*}=\left\{\begin{array}{ll}
\frac{d_{0}+g_{1}}{\cos w_{0}} & \text { for } \quad L \neq 0  \tag{8}\\
0 & \text { for } \quad L=0
\end{array}, \quad d_{1}^{*}=\frac{d_{1}-g_{1}+g_{2}}{\cos w_{1}} .\right.
$$

In Eqs. (8) we assume the conventional zero oblique distance $d_{0}^{*}$ in the case of an object being located at infinity $(L=0)$.

## 3. Astigmatic rays

The formulae given by Young concern the extremely thin pencil of rays in two perpendicular planes: meridional and sagittal. From his formulae it is evident that the pencil of rays performs differently in both planes producing astigmatism as the result. Astigmatism control is a difficult task for the designers of optical systems. In the case of ophthalmic glasses the situation is easier because in principle it is the only aberration that requires correction. Other aberrations, such as distortion or transversal chromatism in the medium power range are rather small and can remain uncorrected.

Less known is the angular version of Young's formulae. In this version, the auxiliary angles $\delta_{m} w$ and $\delta_{s} w$ and differential heights $\delta_{m} h$ and $\delta_{s} h$ are introduced in two perpendicular planes. Thus the formulae take the following form:

$$
\begin{align*}
& n^{\prime} \cos j^{\prime} \delta_{m} w^{\prime}-n \cos j \delta_{m} w=\delta_{m} h\left(n^{\prime} \cos j^{\prime}-n \cos j\right) c \\
& \delta_{m} h_{+1} \cos j_{+1}=\delta_{m} h \cos j^{\prime}-d^{*} \delta_{m} w \\
& n^{\prime} \delta_{s} w^{\prime}-n \delta_{s} w=\delta_{s} h\left(n^{\prime} \cos j^{\prime}-n \cos j\right) c \\
& \delta_{s} h_{+1}=\delta_{s} h-d^{*} \delta_{s} w \tag{9}
\end{align*}
$$

In Equation (9) $n$ and $n^{\prime}$ denote the refractive indices, and subscript +1 denotes the next surface of the system. This version simplifies the notation reducing by one
exponent of the cosine present in the original Young's formulae. Further we will take advantage of formulae (9) because they are very convenient to use.

### 3.1. Differential meridional ray

We assume conventionally the entrance differential angle $d_{m} w_{0}$ between the meridional and pupil rays as equal to

$$
\delta_{m} w_{0}=\left\{\begin{array}{ccc}
-0.01 & \text { for } & L \neq 0  \tag{10}\\
0 & \text { for } & L=0
\end{array}\right.
$$

For further consideration it would be favourable to increase the number of angular parameters describing the meridional ray. We will introduce as variables the differential angles $\delta_{m} j_{1}$ and $\delta_{m} j_{2}$, respectively, for the consecutive surfaces of the glass. After differentiation of the refraction law we obtain the following relation between the angles of incidence and refraction

$$
\begin{equation*}
\delta_{m} j^{\prime}=\frac{n \cos j}{n^{\prime} \cos j^{\prime}} \delta_{m} j \tag{11}
\end{equation*}
$$

By analogy with formula (2) we will introduce the meridional deviations $\delta_{m} D$ of the differential ray as the differences between the differential angles of incidence and refraction. For consecutive surfaces we obtain the following meridional differential deviations:

$$
\begin{align*}
& \delta_{m} D_{1}=\delta_{m} j_{1}-\delta_{m} j_{1}^{\prime} \\
& \delta_{m} D_{2}=\delta_{m} j_{2}-\delta_{m} j_{2} \tag{12}
\end{align*}
$$

Replacing formula (11) for each surface into formulae (12) we obtain the relation between the deviation and variable differential angles:

$$
\begin{align*}
& \delta_{m} D_{1}=\left(1-\frac{\cos j_{1}}{n_{1} \cos j_{1}^{\prime}}\right) \delta_{m} j_{1} \\
& \delta_{m} D_{2}=\left(1-\frac{n_{1} \cos j_{2}}{\cos j_{2}^{\prime}}\right) \delta_{m} j_{2} \tag{13}
\end{align*}
$$

The consecutive differential angle of refraction $\delta_{m} w_{1}$ and $\delta_{m} w_{2}$ with the pupil ray can be calculated from the following formulae:

$$
\begin{align*}
& \delta_{m} w_{1}=\delta_{m} w_{0}+\delta_{m} D_{1} \\
& \delta_{m} w_{2}=\delta_{m} w_{0}+\delta_{m} D_{1}+\delta_{m} D_{2} \tag{14}
\end{align*}
$$

We will conventionally assume the entrance differential height $\delta_{m} h_{0}$ of the meridional ray at the point of intersection with the object plane as equal to

$$
\delta_{m} h_{0}=\left\{\begin{array}{lll}
0 & \text { for } & L \neq 0  \tag{15}\\
1 & \text { for } & L=0
\end{array}\right.
$$

The differential heights $\delta_{m} h_{1}$ and $\delta_{m} h_{2}$ at consecutive glass surfaces obtained from formulae (9) are as follows:

$$
\begin{align*}
& \delta_{m} h_{1}=\frac{\delta_{m} h_{0}-d_{0}^{*} \delta_{m} w_{0}}{\cos j_{1}} \\
& \delta_{m} h_{2}=\frac{\cos j_{1}^{\prime} \delta_{m} h_{1}-d_{1}^{*} \delta_{m} w_{1}}{\cos j_{2}} \tag{16}
\end{align*}
$$

The location of the meridional image $t_{2}$ along the pupil ray does not depend on the entrance angle (Eq. (10)) and height (Eq. (15)) but mainly on the variable angles of incidence $j_{1}$ and $j_{2}$, and differential angles $\delta_{m} j_{1}$ and $\delta_{m} j_{2}$. This location can be calculated from the following formula:

$$
\begin{equation*}
t_{2}^{\prime}=\cos j_{2}^{\prime} \frac{\delta_{m} h_{2}}{\delta_{m} w_{2}} \tag{17}
\end{equation*}
$$

Curvatures $c_{1}$ and $c_{2}$ of glass surfaces calculated from Young's formulae (9) depend on the above-mentioned angular pupil and differential meridional variables in accordance with the following formulae:

$$
\begin{align*}
& c_{1}=\frac{n_{1} \cos j_{1}^{\prime} \delta_{m} w_{1}-\cos j_{1} \delta_{m} w_{0}}{\left(n_{1} \cos j_{1}^{\prime}-\cos j_{1}\right) \delta_{m} h_{1}}, \\
& c_{2}=\frac{\cos j_{2}^{\prime} \delta_{m} w_{2}-n_{1} \cos j_{2} \delta_{m} w_{1}}{\left(\cos j_{2}^{\prime}-n_{1} \cos j_{2}\right) \delta_{m} h_{2}} . \tag{18}
\end{align*}
$$

Curvatures calculated from the differential meridional ray (Eqs. (18)) must conform to the respective curvatures calculated from the pupil ray.

### 3.2. Differential sagittal ray

By analogy to formula (10) we assume conventionally the entrance differential angle $\delta_{s} w_{0}$ of the sagittal ray with the pupil ray to be equal to

$$
\delta_{s} w_{0}=\left\{\begin{array}{ccc}
-0.01 & \text { for } & L \neq 0  \tag{19}\\
0 & \text { for } & L=0
\end{array}\right.
$$

We introduce as variables the differential angles $\delta_{s} j_{1}$ and $\delta_{s} j_{2}$ for consecutive glass surfaces. The refraction of sagittal ray is similar to that of paraxial one. The relation between the angles of incidence and refraction is thus given by the following formula:

$$
\begin{equation*}
\delta_{s} j^{\prime}=\frac{n}{n} \delta_{s} j \tag{20}
\end{equation*}
$$

By analogy to Eq. (12) we introduce the sagittal deviations $\delta_{s} D$ of the differential sagittal ray as the differences between its differential angles of incidence and refraction. For consecutive surfaces we obtain the following sagittal differential deviations:

$$
\begin{align*}
& \delta_{s} D_{1}=\delta_{s} j_{1}-\delta_{s} j_{1}^{\prime} \\
& \delta_{s} D_{2}=\delta_{s} j_{2}-\delta_{s} j_{2}^{\prime} \tag{21}
\end{align*}
$$

Replacing formula (20) taken for each surface into formulae (21) we obtain the relation between these deviations and variable differential angles:

$$
\begin{align*}
& \delta_{s} D_{1}=\left(1-\frac{1}{n_{1}}\right) n_{1} \delta_{s} j_{1}, \\
& \delta_{s} D_{2}=\left(1-n_{1}\right) \delta_{s} j_{2} . \tag{22}
\end{align*}
$$

Consecutive differential angles of refraction $\delta_{s} w_{1}$ and $\delta_{s} w_{2}$ related to the pupil ray can be calculated from the following formulae:

$$
\begin{align*}
& \delta_{s} w_{1}=\delta_{s} w_{0}+\delta_{s} D_{1} \\
& \delta_{s} w_{2}=\delta_{s} w_{0}+\delta_{s} D_{2} . \tag{23}
\end{align*}
$$

The entrance differential height $\delta_{s} h_{0}$ of the sagittal ray at the point of intersection of the pupil ray with the object plane we conventionally assume as equal to

$$
\delta_{s} h_{0}=\left\{\begin{array}{lll}
0 & \text { for } & L \neq 0  \tag{24}\\
1 & \text { for } & L=0
\end{array}\right.
$$

Differential heights $\delta_{s} h_{1}$ and $\delta_{s} h_{2}$ on the consecutive glass surfaces obtained from Eq. (9) are the following:

$$
\begin{align*}
& \delta_{s} h_{1}=\delta_{s} h_{0}-d_{0}^{*} \delta_{s} w_{0} \\
& \delta_{s} h_{2}=\delta_{s} h_{1}-d_{1}^{*} \delta_{s} w_{1} \tag{25}
\end{align*}
$$

The location of sagittal image $s_{2}^{\prime}$ along the pupil ray does not depend on the entrance angle (Eq. (19)) and height (Eq. (24)) but mainly on the variable incident
angles $j_{1}$ and $j_{2}$ and differential angles $\delta_{s} j_{1}$ and $\delta_{s} j_{2}$. This location can be calculated from the following formula:

$$
\begin{equation*}
s_{2}^{\prime}=\frac{\delta_{s} h_{2}}{\delta_{s} w_{2}} \tag{26}
\end{equation*}
$$

The curvatures $c_{1}$ and $c_{2}$ of consecutive glass surfaces depend on the above -mentioned pupil and sagittal angular variables in accordance with the following formulae:

$$
\begin{equation*}
c_{1}=\frac{N \delta_{s} w_{1}-\delta_{s} w_{0}}{\left(N \cos j_{1}^{\prime}-\cos j_{1}\right) \delta_{s} h_{1}}, \quad c_{2}=\frac{\delta_{s} w_{2}-N \delta_{s} w_{1}}{\left(\cos j_{2}^{\prime}-N \cos j_{1}\right) \delta_{s} h_{2}} \tag{27}
\end{equation*}
$$

Curvatures calculated from the differential sagittal ray (Eqs. (27)) must conform to the respective curvatures calculated from pupil (Eq. (6)) and differential meridional (Eq. (18)) rays.

## 4. Conditions of correct performance

Performance of the nonastigmatic ophthalmic glass is characterized by the back vertex power. This power denoted as BVP is a function of construction parameters such as: surface curvatures $c_{1}$ and $c_{2}$, thickness of glass $d_{1}$ and the refractive index $n_{1}$ of glass in accordance with following formula:

$$
\begin{equation*}
\mathrm{BVP}=P_{2}+\frac{P_{1}}{1-0.001 P_{1} \frac{d_{1}}{n_{1}}} \tag{28}
\end{equation*}
$$

Surface powers $P_{1}$ and $P_{2}$ expressed in diopters, found in formula (28), can be calculated from the following formulae:

$$
\begin{equation*}
P_{1}=1000\left(n_{1}-1\right) c_{1}, \quad P_{2}=1000\left(1-n_{1}\right) c_{2} . \tag{29}
\end{equation*}
$$

Perfectly designed positive ophthalmic glass should feature minimum edge thickness $d_{\mathrm{e}}$ at the outer diameter $\Phi$, that depends on geometric construction parameters according to the formula

$$
\begin{equation*}
d_{\mathrm{e}}=d_{1}-x_{1}+x_{2} \tag{30}
\end{equation*}
$$

Sags denoted by $x_{1}$ and $x_{2}$ in Eq. (30) at the height $h=\Phi / 2$ are determined from the formulae:

$$
\begin{equation*}
x_{1}=\frac{h^{2} c_{1}}{1+\sqrt{1-h^{2} c_{1}^{2}}}, \quad x_{2}=\frac{h^{2} c_{2}}{1+\sqrt{1-h^{2} c_{2}^{2}}} \tag{31}
\end{equation*}
$$

The enterence positive glass edge thickness concerns the initial situation before we start to process the glass to obtain different outer shapes, e.g., oval, pilot or square. Negative ophthalmic glasses have fixed minimum center thickness along the optical axis.

The condition for correct performance of ophthalmic glass is the correct location of the exit pupil $p_{2}^{\prime}$. This location is calculated from the pupil ray with the use of formulae (3) and (5) as follows:

$$
\begin{equation*}
p_{2}^{\prime}=\frac{M^{\prime}}{\sin w_{2}} . \tag{32}
\end{equation*}
$$

The most important parameter characterizing the performance of ophthalmic glasses is astigmatism (Ast) for the characteristic angle of view $w_{\mathrm{ch}}$. Astigmatism expressed in diopters (D) is calculated based on the location of images determined in formulae (17) and (26)

$$
\begin{equation*}
\operatorname{Ast}\left(w_{\mathrm{ch}}\right)=\left(\frac{1}{t_{2}^{\prime}}-\frac{1}{s_{2}^{\prime}}\right) 1000 \tag{33}
\end{equation*}
$$

The condition for correct performance of the model ophthalmic glasses is zero astigmatism Ast $\left(w_{c h}\right)=0 \mathrm{D}$ in the characteristic angle of view. According to formulae given earlier all conditions for correct performance of glasses can be presented in the form of functions of linear and angular variables.

## 5. Algebraic method for the design of ophthalmic glasses

All dependences given in this work were defined as mutually nested functions of angular and linear variables. Owing to that we can describe very complex dependences in a simple and clear manner and solve them with the use of advanced professional software. In this work, the Mathcad software was used. The exact algebraic method of design of nonastigmatic spherical glasses consists in solving the system of nonlinear equations.

In the case of positive glasses it is necessary to solve the system of 8 nonlinear equations with 8 unknowns. The unknowns include:

- the angles of incidence at the glass surface of: the pupil rays $j_{1}$ and $j_{2}$, the differential meridional rays $j_{m 1}$ and $j_{m 2}$, and the sagittal rays $j_{s 1}$ and $j_{s 2}$;
- two linear parameters: center thickness $d_{1}$ of the glass along the optical axis, and the shortest distance $M_{1}$ of the incident ray from the vertex of the first surface.

Nonlinear equations concern: required back vertex power, location of the exit pupil, the minimum edge thickness of glass, correction of dioptric astigmatism to zero, conformity of curvatures of the first surface calculated for the meridional and pupil rays, conformity of curvatures of the second surface calculated for the meridional and pupil rays, conformity of curvatures of the first surface calculated for the sagittal and
pupil rays, and conformity of curvatures of the second surface calculated for the sagittal and pupil rays.

To start the calculation it is necessary to fix the values of global constants and initial values of variables. Global constants are: refractive index $n_{1}$ of glass, object vergence in diopters $L$ and the outer glass diameter $\boldsymbol{\Phi}$. Initial values of variables are determined with the use of the trial-and-error method. Once set the values are useful for a large group of glasses of various powers because the solution only slightly depends on initial values.

Equations of conformity of the curvatures of surfaces calculated with the use of different rays should be multiplied by weight coefficients to reduce the errors to minimum. Such an operation guarantees that the parameters of all three rays concern the same and common optical system.

After determination of unknowns the calculations of curvatures or radii of curvatures can be made with the use of an arbitrary ray. For verification purposes usually they are calculated by means of three methods (rays) in accordance with formulae (6), (18) and (27).

In the case of negative glasses the algebraic method of design becomes slightly simpler. The number of nonlinear equations and unknowns is reduced to 7. The thickness of glass is not a variable any more and remains in the group of global variables.

## 6. Model nonastigmatic spherical glasses

The present method of design of nonastigmatic spherical ophthalmic glasses was used for exemplary calculations of the construction parameters of model ophthalmic glasses of a given range of back vertex power, which completely fulfil all conditions of correct performance. Nonastigmatic positive and negative ophthalmic glasses were designed. The following assumptions were made: range of back vertex power from 0 to $\pm 7$ in steps of 0.25 D , outer diameter $\Phi=65 \mathrm{~mm}$, material: Columbian resin CR39 with $n_{\mathrm{e}}=1.500$, location of the exit pupil $p_{2}^{\prime}=25 \mathrm{~mm}$, minimum edge thickness for the positive glasses $d_{\mathrm{e}}=0.8 \mathrm{~mm}$, characteristic one-side angle of view $w_{\mathrm{ch}}=15^{\circ}$, dioptric astigmatism equal to zero for characteristic angle of view, and calculation for three object vergences $L=0,-2,-4 \mathrm{D}$ (distance from the object $\propto 500$ and 250 mm , respectively).

Assumed angle $w_{\text {ch }}=15^{\circ}$ reflects approximately the situation where the text line on the portrait A4 page is read from the distance of $250 \mathrm{~mm}(L=-4 \mathrm{D})$ or the text line on the landscape A4 page is read from the distance of $500 \mathrm{~mm}(L=-2 \mathrm{D})$. Calculated construction parameters (radii of surfaces $R_{1}, R_{2}$ and thickness $d_{1}$ ) of nonastigmatic positive glasses can be found in Tab. 1.

Table 1 presents the solutions with the longest radii (Ostwald type). It is a bit difficult to obtain this kind of glasses with zero astigmatism in the end of BVP range. The solution of Wollaston type of glasses can be avoided when we assume certain value of residual astigmatism lower than the eye's tolerance. As we see from Tab. 1, thicknesses determined in BVP range to 1 D are too small from technological

Table 1. Model positive spherical ophthalmic glasses, diameter $\Phi=65 \mathrm{~mm}$, material CR39.

point of view but they do follow earlier assumption ( $d_{\mathrm{e}}=0.8 \mathrm{~mm}$ ). Results of calculation confirm earlier observation that the radii of glass curvatures elongate when the object is getting closer to the eye. However, the assumption of common solution for $L=-4 \mathrm{D}$ independent of object location leads to the impairment of visual comfort for $L=0 \mathrm{D}$. It is a good idea to assume common solution for $L=-2 \mathrm{D}$ because the present astigmatism in the characteristic angle for $L=0 \mathrm{D}$ and $L=-4 \mathrm{D}$ is then lower than the astigmatism tolerances of the eye equal $0.12-0.15 \mathrm{D}$.

Table 2 presents the calculated construction parameters of nonastigmatic negative ophthalmic glasses, which also fulfil all assumptions. Zero glasses ( $B V=0 \mathrm{D}$ ) were also added to this group. As it is evident from Tab. 2 thicknesses of negative glasses

Table 2. Model negative spherical ophthalmic glasses, diameter $\Phi=65 \mathrm{~mm}$, material CR39.

were adopted with the use of step method starting from 1.8 mm , which simulates existing constructions. Solution of negative glasses of Ostwald type for the entire range of BVP does not bring too much trouble. Table 2 confirms the tendency of radii to elongate when the object is getting closer to the eye.

## 7. Conclusions

It is evident from this work that designing the nonastigmatic spherical ophthalmic lenses with the use of exact algebraic method instead of the simplified 3rd order
methods is possible. The method was tested for correctness in exemplary calculations of low-diopter nonastigmatic spherical glass of both positive and negative BVP.

The results concern the theoretical solutions of model glasses because they do not include any technological simplifications introduced to reduce the tooling.
